Goal

We study some important properties of value functions and MDPs.

- Bellman equation: $V^\pi = r^\pi + \gamma \mathcal{P}^\pi V^\pi$.
- Bellman operator: $T^\pi : V \mapsto r + \gamma \mathcal{P}^\pi V$.
 - ▶ Monotonicity: $V_1 \leq V_2 \Rightarrow TV_1 \leq TV_2$.
 - ▶ Contraction: $\|TV_1 - TV_2\|_\infty \leq \gamma \|V_1 - V_2\|_\infty$.
- Focus on discounted tasks
- We show important consequences such as
 - ▶ The uniqueness of the solution to the Bellman equations: If $V = T^\pi V$, then $V = V^\pi$.
 - ▶ Error bounds on value error: $\|V - V^*\|_\infty \leq \frac{\|V - T^*V\|_\infty}{1 - \gamma}$.
 - ▶ Fixed point of T^* is the optimal value function: $V^* = V^{\pi^*}$.
- The meaning of $\mathcal{P}f$, $\mathcal{P}^{\pi_{1:m}}$, and $T^{\pi_1}T^{\pi_2} \dots T^{\pi_m}V$ notations.

We refer to these frequently in studying and analyzing RL/Planning algorithms.

Learning Objectives

You need to

- Remember: Bellman Equation, Bellman Operator, Greedy Policy, Banach Fixed Point theorem
- Understand: What do Bellman equation encode and why do we use them? What do contraction and monotonicity mean?
- Apply: Contraction property

Bellman Equations

Return

Consider the sequence of rewards $(R_1, R_2, \dots)$ generated after the agent starts at state $X_1 = \underline{x}$ and follows policy π . Given the discount factor $0 \leq \gamma < 1$, the return is

$$\underline{G_t^\pi} \triangleq \sum_{k \geq t} \gamma^{\underline{k-t}} \underline{R_k}.$$

Return

$$G_t^\pi \triangleq \sum_{k \geq t} \gamma^{k-t} R_k.$$

Return is a random variable (r.v.), so even when we follow the same policy, we might get different trajectories in two different runs.

Return

$$G_t^\pi \triangleq \sum_{k \geq t} \gamma^{k-t} R_k.$$

Here we get two trajectories (or rollouts):

- $X_t = \underline{3}, R_t = \underline{R(3)}, X_{t+1} = \underline{2}, R_{t+1} = \underline{R(2)}, X_{t+2} = 3, R_{t+2} = R(3), X_{t+3} = 4, R_{t+3} = R(4), \dots$, so the realized return from time t onwards is $\underline{R(3)} + \gamma \underline{R(2)} + \gamma^2 \underline{R(3)} + \gamma^3 \underline{R(4)} + \dots$
- $X_t = 3, R_t = \underline{R(3)}, X_{t+1} = \underline{4}, R_{t+1} = \underline{R(4)}, X_{t+2} = 5, R_{t+2} = R(5), X_{t+3} = 5, R_{t+3} = R(5), \dots$, so the realized return from time t onwards is $R(3) + \gamma \underline{R(4)} + \gamma^2 \underline{R(5)} + \gamma^3 \underline{R(5)} + \dots$

Recursive Property of Return

$$\overbrace{R_1 + \gamma R_2 + \gamma^2 R_3 + \gamma^3 R_4 + \dots}^{=G_1^\pi} = \underbrace{\gamma R_2 + \gamma^2 R_3 + \gamma^3 R_4 + \dots}_{=\gamma G_2^\pi}$$

Comparing G_t^π and G_{t+1}^π , we observe that

$$\Rightarrow G_t^\pi = R_t + \gamma G_{t+1}^\pi. \quad (1)$$

Interpretation: The return at the current time is equal to the immediate reward plus the *discounted* return at the next time step.

- Return is a random variable (r.v.).
- If we repeat the experiment from the same state x , the return would be different.
- Its distribution, however, is the same.
- Q: When would repeated runs lead to the same return?

From Return to the Bellman Equation

We take (conditional) expectation of G_t^π (conditioned on state x), and expand the return as in (1):

$$\begin{aligned}
 V^\pi(\underline{x}) &= \mathbb{E}[\underline{G}_t^\pi \mid \underline{X}_t = \underline{x}] \\
 &= \mathbb{E}[\underline{R}_t + \gamma \underline{G}_{t+1}^\pi \mid \underline{X}_t = \underline{x}] \\
 &= \mathbb{E}[R(\underline{X}_t, \underline{A}_t) \mid \underline{X}_t = \underline{x}] + \gamma \mathbb{E}[\underline{G}_{t+1}^\pi \mid \underline{X}_t = \underline{x}] \\
 &= \underline{r}^\pi(\underline{x}) + \gamma \mathbb{E}[\underline{V}^\pi(\underline{X}_{t+1}) \mid \underline{X}_t = \underline{x}].
 \end{aligned} \tag{2}$$

Neither side is random anymore!

Expanding $\mathbb{E}[V^\pi(X_{t+1}) \mid X_t = x]$

What does $\mathbb{E}[V^\pi(X_{t+1}) \mid X_t = x]$ mean?

It is the expected value of $V^\pi(X_{t+1})$ when

- the agent is at state x at time t
- chooses action $A \sim \pi(\cdot|x)$
- goes to a state $X_{t+1} \sim \mathcal{P}(\cdot|x, A)$

That is:

$$\rightarrow \mathbb{E}[V^\pi(X_{t+1}) \mid X_t = x] = \int \mathcal{P}(\underline{dx'}|\underline{x}, \underline{a}) \pi(\underline{da}|x) \underline{V^\pi(x')}. \quad (3)$$

For countable state-action spaces, we have

$$\mathbb{E}[V^\pi(X_{t+1}) \mid X_t = x] = \sum_{\underline{x'}, \underline{a}} \mathcal{P}(\underline{x'}|\underline{x}, \underline{a}) \pi(\underline{a}|x) \underline{V^\pi(x')}.$$

For deterministic π , this is simply $\sum_{x'} \mathcal{P}(x'|x, \underline{\pi(x)}) V^\pi(x')$.

Bellman Equation for a Policy π

By (2) and (3), we get that for any $x \in \mathcal{X}$, we have

$$V^\pi(x) = \underbrace{r^\pi(x)} + \underbrace{\gamma}_{\text{discount factor}} \int \underbrace{\mathcal{P}(dx'|x, a)}_{\text{transition prob}} \underbrace{\pi(da|x)}_{\text{policy}} \underbrace{V^\pi(x')}_{\text{value of next state}}. \quad (4)$$

This is the **Bellman equation** for a policy π .

Interpretation: The value of following a policy π starting from the state x is the reward that the π -following agent receives at that state plus the discounted average (expected) value that the agent receives at the next-state.

Bellman Equation for a Policy π

Using the $\mathcal{P}^\pi$ notation:

$$V^\pi(x) = r^\pi(x) + \gamma \int \underline{\mathcal{P}^\pi(dx'|x)} V^\pi(x').$$

Or even more compactly,

$$V^\pi = r^\pi + \gamma \mathcal{P}^\pi V^\pi.$$

Remark

Recall that $(\mathcal{P}^\pi)(A|x)$ $\triangleq \int_{\mathcal{X}} \mathcal{P}(dy|x, a) \pi(da|x) \mathbb{I}_{\{y \in A\}}$

Bellman Equation for a Policy π – Example

The Bellman equations are:

$$V^\pi(\underline{x_1}) = \underline{r(x_1)} + \gamma [\underline{\mathcal{P}(x_1|x_1)} \underline{V^\pi(x_1)} + \underline{\mathcal{P}(x_2|x_1)} \underline{V^\pi(x_2)}]$$

$$\rightarrow V^\pi(\underline{x_2}) = r(x_2) + \gamma [\underline{\mathcal{P}(x_1|x_2)} \underline{V^\pi(x_1)} + \underline{\mathcal{P}(x_2|x_2)} \underline{V^\pi(x_2)}]$$

In matrix form, we can write it as

$$\rightarrow \begin{bmatrix} V_1^\pi \\ V_2^\pi \end{bmatrix} = \begin{bmatrix} r_1 \\ r_2 \end{bmatrix} + \gamma \begin{bmatrix} p_{11} & p_{12} \\ p_{21} & p_{22} \end{bmatrix} \begin{bmatrix} V_1^\pi \\ V_2^\pi \end{bmatrix}$$

Bellman Equation for a Policy π (Q^π)

The Bellman equation for the action-value function Q^π :

$$\begin{aligned}
 Q^\pi(x, a) &= r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) V^\pi(x') \\
 &= r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) \pi(da'|x') Q^\pi(x', a').
 \end{aligned} \tag{5}$$

Handwritten annotations: Green arrows point from $Q^\pi(x, a)$ to $r(x, a)$ and $Q^\pi(x', a')$. Blue arrows point from $\mathcal{P}(dx'|x, a)$ to x' and from $V^\pi(x')$ to $Q^\pi(x', a')$. A green bracket on the right side of the equation is labeled $x \rightarrow Q^\pi(x, a)$.

More compactly:

$$Q^\pi = r + \gamma \mathcal{P} V^\pi,$$

Handwritten annotations: A green arrow points from Q^π to the compact equation. To the right, $V^\pi(x) \leftarrow$ is written with a note: "actions are selected according to π ".

with the understanding that V^π and Q^π are related as

$$\underline{V^\pi(x) = \int \pi(da|x) Q^\pi(x, a)}.$$

Handwritten annotations: $V^\pi(x) = \int \pi(da|x) Q^\pi(x, a) = \sum \pi(a|x) Q^\pi(x, a)$. A blue arrow points from the integral term to the compact equation.

Remark

The difference with the Bellman equation for V^π is that the choice of action at the first time step is pre-specified, instead of being selected by policy π .

Handwritten notes:

- to π :
- $A \sim \pi(\cdot|x)$
- $[A = \pi(x)]$

Example

Write down the Bellman equation for π_1 , which always selects action a_1 at x_0 .

$$V^{\pi_1}(\underline{x_0}) = Q^{\pi_1}(\underline{x_0}, \underline{a_1}) = \gamma [0.8V^{\pi_1}(\underline{x_1}) + 0.2V^{\pi_1}(\underline{x_2})],$$

$$V^{\pi_1}(\underline{x_1}) = \underline{7} + \gamma V^{\pi_1}(\underline{x_2}),$$

$$V^{\pi_1}(\underline{x_2}) = \underline{2} + \gamma V^{\pi_1}(\underline{x_0}).$$

Example

We can solve a system of linear equations. After some calculations, we get that

$$[5 - \gamma^2(1 + 4\gamma)]V^{\pi_1}(x_0) = 2\gamma(15 + 4\gamma).$$

For $\gamma = 3/4$, we have $V^{\pi_1}(x_0) = \frac{108}{11} \approx 9.82$.

Q: What is $Q^{\pi_1}(x_0, a_2)$? $= 2 + \gamma V^{\pi_1}(x_2)$

Exercise: Let $\pi_2(x_0) = a_2$. What is $V^{\pi_2}(x_0)$?

Optimal Policy and Value Function

Recall that the optimal policy π^* is a policy that satisfies $\pi^* \geq \pi$ for any (stationary Markov) policy π . This means that

$$\underline{\pi^*} \leftarrow \operatorname{argmax}_{\underline{\pi \in \Pi}} \underline{V^{\pi}}.$$

Given an optimal policy, the optimal value function would be V^{π^*} .

Bellman Equations for Optimal Value Functions

Does the optimal value function V^{π^*} satisfy a recursive relation similar to the Bellman equation for a policy π ?

Short answer: Yes!

But we have to be a bit careful. Why?! We have to go through a few steps of argument.

Bellman Equations for Optimal Value Functions

The argument goes through three claims:

- 1 There exists a unique value function V^* that satisfies the following equation: For any $x \in \mathcal{X}$, we have

$$V^*(x) = \max_{a \in \mathcal{A}} \left\{ \underline{r(x, a)} + \underline{\gamma} \int \mathcal{P}(\underline{dx'} | x, a) \underline{V^*(x')} \right\}. \quad (6)$$

This equation is called the Bellman optimality equation for the value function.

- 2 V^* is indeed the same as V^{π^*} , the optimal value function when π is restricted to be within the space of stationary policies.
- 3 For discounted continuing MDPs, we can always find a stationary policy that is optimal within the space of all stationary and non-stationary policies.

In summary: V^* exists and is equal to V^{π^*} .

Bellman Equations for Optimal Value Functions (Q^*)

Optimal action-value function:

$$Q^*(x, a) = r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) \max_{a' \in \mathcal{A}} Q^*(x', a'). \quad (7)$$

Solutions of the Bellman Equations?

We have defined the Bellman equations for a fixed policy π and the Bellman optimality equation. Some reasonable questions:

- Is there only one solution V^π (or Q^π) satisfying (4) and (5)?
- Is there only one solution V^* (or Q^*) satisfying the Bellman optimality equations (6) and (7)?

We shall prove that their solutions are unique. We need some tools before doing so.

Greedy Policy

Optimal Policy from the Optimal Value Function

- If we know V^* or Q^* , we can find an optimal policy π^* .
- It is a deterministic policy.
- For any $x \in \mathcal{X}$, the optimal policy is

$$\begin{aligned}
 \underline{\pi^*(x)} &= \operatorname{argmax}_{a \in \mathcal{A}} \underline{Q^*(x, a)} \quad \leftarrow \\
 &= \operatorname{argmax}_{\underline{a \in \mathcal{A}}} \left\{ \underline{r(x, a)} + \gamma \int \mathcal{P}(\underline{dx'} | \underline{x, a}) \underline{V^*(x')} \right\}.
 \end{aligned}$$

Optimal Policy from the Optimal Value Function

$$\pi^*(x) = \operatorname{argmax}_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) V^*(x') \right\}.$$

Interpretation: Suppose that the agent is at state x . To act optimally,

- It needs to act optimally both at the current time step (Now) and in the Future time steps.
- Suppose that we know that the agent is going to act optimally in the Future. This means that when it get to the next state $X' \sim \mathcal{P}(\cdot | x, a)$,
 - ▶ it follows the optimal policy π^* .
 - ▶ The value of following the optimal policy is going to be $V^*(X')$.
- (continued ...)

Optimal Policy from the Optimal Value Function

$$\pi^*(x) = \operatorname{argmax}_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) V^*(x') \right\}.$$

Interpretation: Suppose that the agent is state x . To act optimally,

- ...
- Since we do not know where the agent will be at the next time step, the expected performance of acting optimally in the Future is $\int \mathcal{P}(\mathrm{d}x' | x, a) V^*(x')$.
- As we are dealing with discounted tasks, the performance of the agent at the current state x is going to be $r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) V^*(x')$.
- To act optimally Now, the agent should choose an action that maximizes this value.

Greedy Policy

The mapping that selects an action by choosing the maximizer of the (action-) value function is called the greedy policy.

- For $Q \in \mathcal{B}(\mathcal{X} \times \mathcal{A})$, the greedy policy $\pi_g : \mathcal{X} \times \mathcal{B}(\mathcal{X} \times \mathcal{A}) \rightarrow \mathcal{A}$ is

$$\pi_g(x; Q) = \operatorname{argmax}_{a \in \mathcal{A}} Q(x, a).$$

- For $V \in \mathcal{B}(\mathcal{X})$, the greedy policy is

$$\pi_g(x; V) = \operatorname{argmax}_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(dx' | x, a) V(x') \right\}.$$

- We use $\pi_g(V)$ and $\pi_g(Q)$ to denote the greedy policies based on V and Q . These are functions from $\mathcal{X}$ to $\mathcal{A}$.
- The value function of the greedy policy w.r.t. the optimal value function is the optimal value function: $V_{\pi_g(V^*)} = V_{\pi_g(Q^*)} = V^*$.
- Q: What is the difference between greedy policy and ε -greedy policy?

Greedy Policy

Intuition behind the greedy policy:

- Action selection based on the **local** information.
- Does not look at all of the future possibilities.
- Only one step ahead (for V) or even no-step ahead (for Q) in order to pick the action. This is myopic.
- Given V^* or Q^* , however, the selected action is going to be the optimal one.
- This is because the optimal value functions encodes the information about the future, so we do not need to explicitly consider all possible futures.

Bellman Operators

Bellman Operators

- The Bellman equations can be seen as the fixed point equation of certain operators known as the Bellman operators.
- Let us review what an operator is.
- An operator (or mapping) $L : \mathcal{Z} \rightarrow \mathcal{Z}$ takes a member of space $\mathcal{Z}$ and returns another member of $\mathcal{Z}$.
 - ▶ If $\mathcal{Z} = \mathbb{R}$ and $L : z \mapsto z^2$. So $L(5) = 25$ (this is the usual function).
 - ▶ If $\mathcal{Z}$ is the space of smooth functions defined on domain $\mathbb{R}$, $L : z \mapsto \frac{d}{dx}z$, is the differentiation operator. So $L(\sin(x)) = \cos(x)$.

Bellman Operators

Definition (Bellman Operators for policy π)

Given a policy $\pi : \mathcal{X} \rightarrow \mathcal{M}(\mathcal{A})$, the Bellman operators $T^\pi : \mathcal{B}(\mathcal{X}) \rightarrow \mathcal{B}(\mathcal{X})$ and $T^\pi : \mathcal{B}(\mathcal{X} \times \mathcal{A}) \rightarrow \mathcal{B}(\mathcal{X} \times \mathcal{A})$ are defined as the mappings that take V (or Q) and return new functions defined for all $x \in \mathcal{X}$ (for V) or all $(x, a) \in \mathcal{X} \times \mathcal{A}$ (for Q):

$$\begin{aligned}
 (T^\pi V)(x) &\triangleq r^\pi(x) + \gamma \int \mathcal{P}(dx'|x, a) \pi(da|x) V(x'), \\
 (T^\pi Q)(x, a) &\triangleq r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) \pi(da'|x') Q(x', a'),
 \end{aligned}$$

Bellman Operators

If π is deterministic:

$$(T^\pi V)(x) \triangleq r^\pi(x) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, \underline{\pi(x)}) V(x'),$$

$$(T^\pi Q)(x, a) \triangleq r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) Q(x', \underline{\pi(x')}).$$

Bellman Operators – Example

$$(T^\pi V)(x) \triangleq \underline{r^\pi(x)} + \gamma \int \underline{\mathcal{P}(dx'|x, \pi(x))} V(x'),$$

Given a vector $\underline{V} = [\underline{V_1}, \underline{V_2}]^\top$, the effect of Bellman operator $\underline{T^\pi}$ on it is

$$\underline{T^\pi V} \triangleq \begin{bmatrix} (T^\pi V)(\underline{x_1}) \\ (T^\pi V)(\underline{x_2}) \end{bmatrix} = \begin{bmatrix} \underline{r_1} \\ \underline{r_2} \end{bmatrix} + \gamma \begin{bmatrix} p_{11} & p_{12} \\ \underline{p_{21}} & p_{22} \end{bmatrix} \begin{bmatrix} \underline{V_1} \\ \underline{V_2} \end{bmatrix}$$

Note that this is different from the Bellman equation, but looks similar.

Q: What is the difference?

Bellman Operators and Bellman Equation

Recall that

$$\begin{aligned}\underline{V}^\pi(x) &= \underline{r}^\pi(x) + \gamma \int \mathcal{P}(\mathrm{d}x'|x, a) \pi(\mathrm{d}a|x) \underline{V}^\pi(x'), \\ Q^\pi(x, a) &= r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x'|x, a) \pi(\mathrm{d}a'|x') Q^\pi(x', a').\end{aligned}$$

Using the Bellman operator $\underline{T}^\pi$, we can write them compactly as

$$\begin{cases} \underline{V}^\pi = \underline{T}^\pi \underline{V}^\pi, \\ \underline{Q}^\pi = \underline{T}^\pi \underline{Q}^\pi. \end{cases}$$

This is a compact form of the Bellman equations.

Bellman Optimality Operators

Definition (Bellman Optimality Operators)

The Bellman operators $T^* : \mathcal{B}(\mathcal{X}) \rightarrow \mathcal{B}(\mathcal{X})$ and $T^* : \mathcal{B}(\mathcal{X} \times \mathcal{A}) \rightarrow \mathcal{B}(\mathcal{X} \times \mathcal{A})$ are defined as the mapping

$$\begin{aligned} (T^*V)(x) &\triangleq \max_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(dx' | x, a) V(x') \right\}, \\ (T^*Q)(x, a) &\triangleq r(x, a) + \gamma \int \mathcal{P}(dx' | x, a) \max_{a' \in \mathcal{A}} Q(x', a'), \end{aligned}$$

defined for all $x \in \mathcal{X}$ (for V) or all $(x, a) \in \mathcal{X} \times \mathcal{A}$ (for Q).

Bellman Optimality Operators and Bellman Optimality Equations

Comparing the definition of the Bellman optimality operators with the Bellman equations

$$\left| \begin{aligned} \underline{V}^*(x) &= \max_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) \underline{V}^*(x') \right\}, \\ Q^*(x, a) &= r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) \max_{a' \in \mathcal{A}} Q^*(x', a'), \end{aligned} \right.$$

we see that

$$\begin{aligned} T^{\pi} V_1 &= r + \gamma P^{\pi} V_1 \\ \uparrow \\ \begin{bmatrix} 1 \\ c \end{bmatrix} &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} + \gamma \begin{bmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{3} & \frac{2}{3} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\ V^* &= T^* V^*, \\ Q^* &= T^* Q^*. \end{aligned}$$

$$= \begin{bmatrix} 1 + \gamma(\frac{1}{2} \times 1 + \frac{1}{2} \times 0) \\ 0 + \gamma(\frac{1}{3} \times 1 + \frac{2}{3} \times 0) \end{bmatrix} = \begin{bmatrix} 1 + \frac{\gamma}{2} \\ \frac{\gamma}{3} \end{bmatrix}.$$

Properties of the Bellman Operators

Properties of the Bellman Operators

The Bellman operators have some important properties. The properties that matters for us the most are

- Monotonicity
- Contraction

They are used in

- basic proofs such as the existence and uniqueness of the solution to the Bellman equations.
- (directly or indirectly) design of many RL/Planning algorithms.

Monotonicity

For two functions $V_1, V_2 \in \mathcal{B}(\mathcal{X})$, we use $V_1 \leq V_2$ if and only if $V_1(x) \leq V_2(x)$ for all $x \in \mathcal{X}$.

- $V_3 \leq V_1$ and $V_3 \leq V_2$,
- Neither $V_2 \leq V_1$, nor $V_1 \leq V_2$.

Monotonicity

Lemma (Monotonicity)

Fix a policy π . If $V_1, V_2 \in \mathcal{B}(\mathcal{X})$, and $V_1 \leq V_2$, then we have

$$\rightarrow T^\pi V_1 \leq T^\pi V_2,$$

$$\rightarrow T^* V_1 \leq T^* V_2.$$

Monotonicity (Proof)

We only prove the first claim. Let us expand $T^\pi V_1$. As $V_1(x') \leq V_2(x')$ for any $x' \in \mathcal{X}$, we get that for any $x \in \mathcal{X}$,

$$\begin{aligned}
 (T^\pi V_1)(x) &= \underbrace{r^\pi(x)} + \gamma \int \mathcal{P}^\pi(dx'|x) \underbrace{V_1(x')}_{\leq V_2(x')} \\
 &\leq \underbrace{r^\pi(x)} + \gamma \int \mathcal{P}^\pi(dx'|x) \underbrace{V_2(x')} = (T^\pi V_2)(x).
 \end{aligned}$$

Therefore, $T^\pi V_1 \leq T^\pi V_2$.

Tips and Tricks

Sometimes expanding the definition of the Bellman operator is all that you need to get started in the proof.

Contraction Mapping and Banach Fixed Point Theorem

Another important property of the Bellman operators is their **contraction** property.

What does that mean?

Let us review some mathematical background before proving that the Bellman operators are contraction. We quote several results from **Hunter and Nachtergaele [2001]**.

Metric

Definition (Metric)

A metric or a distance function on $\mathcal{Z}$ is a function $d : \mathcal{Z} \times \mathcal{Z} \rightarrow \mathbb{R}$ with the following properties:

- $d(x, y) \geq 0$ for all $x, y \in \mathcal{Z}$; and $d(x, y) = 0$ if and only if $x = y$.
- $d(x, y) = d(y, x)$ for all $x, y \in \mathcal{Z}$ (symmetry).
- $d(x, y) \leq d(x, z) + d(z, y)$ for all $x, y, z \in \mathcal{Z}$ (triangle inequality).

A metric space $(\mathcal{Z}, d)$ is a set $\mathcal{Z}$ equipped with a metric d .

Example

Let $\mathcal{Z} = \mathbb{R}$ and $d(x, y) = |x - y|$. These together define a metric space $(\mathbb{R}, d)$.

Norm

Definition (Norm)

A norm on a linear space $\mathcal{Z}$ is a function $\|\cdot\| : \mathcal{Z} \rightarrow \mathbb{R}$ with the following properties:

- (non-negative) For all $x \in \mathcal{Z}$, $\|x\| \geq 0$. $|x| \quad |5| \geq 0$
- (homogenous) For all $x \in \mathcal{Z}$ and $\lambda \in \mathbb{R}$, $\|\lambda x\| = |\lambda| \|x\|$. $|3 \times 5| = (3) \cdot (5)$
- (triangle inequality) For all $x, y \in \mathcal{Z}$, $\|x + y\| \leq \|x\| + \|y\|$. $|3 - 5| \leq |3| + |5|$
- (strictly positive) If for a $x \in \mathcal{Z}$, we have that $\|x\| = 0$, it implies that $x = 0$. $|x| = 0 \Rightarrow x = 0$

Remark

We can use a norm to define a distance between two points in a linear space $\mathcal{Z}$ by defining $d(x, y) = \|x - y\|$. This gives us a metric space $(\mathcal{Z}, d)$.

Norm

Example

Let $\mathcal{Z} = \mathbb{R}^d$ ($d \geq 1$). The following norms are often used:

$$\|x\|_p = \sqrt[p]{\sum_{i=1}^d |x_i|^p}, \quad 1 \leq p < \infty,$$

$$\|x\|_\infty = \max_{i=1, \dots, d} |x_i|.$$

These are the ℓ_p -norms.

Question: What is the ℓ_1 , ℓ_2 , and ℓ_∞ norms of the vector $x = (-1, 3, -2)$?

$$\|x\|_1 = 6$$

$$\|x\|_2 = \sqrt{14}$$

$$\|x\|_\infty = 3$$

Norm

Example

Consider the space of continuous functions with domain $[0, 1]$. It is denoted by $\mathcal{C}([0, 1])$. This plays the role of $\mathcal{Z}$. We define the following norm for a function $f \in \mathcal{C}([0, 1])$:

$$\|f\|_{\infty} = \sup_{x \in [0, 1]} |f(x)|.$$

This is called the supremum or uniform norm. Given this norm, $(\mathcal{C}([0, 1]), \|\cdot\|_{\infty})$ would be a normed linear space.

Question: What are the supremum norms of the following functions defined over $[0, 1]$:

- $f_k(x) = \sin(2\pi kx)$ with $k \in \{1, 2, \dots\}$
- $f_c(x) = cx$ with $c \in \mathbb{R}$

Norm

For $V \in \mathcal{B}(\mathcal{X})$ and $Q \in \mathcal{B}(\mathcal{X} \times \mathcal{A})$, their supremum norms are

$$\left\{ \begin{array}{l} \|V\|_{\infty} = \sup_{x \in \mathcal{X}} |V(x)|, \\ \|Q\|_{\infty} = \sup_{(x,a) \in \mathcal{X} \times \mathcal{A}} |Q(x,a)|, \end{array} \right.$$

This is simply the maximum value of the value function V or action-value function Q over the state or state-action spaces.

Contraction Mapping

Definition (Contraction Mapping)

Let $(\mathcal{Z}, d)$ be a metric space. A mapping $L : \mathcal{Z} \rightarrow \mathcal{Z}$ is a contraction mapping (or contraction) if there exists a constant $0 \leq a < 1$ such that for all $z_1, z_2 \in \mathcal{Z}$, we have

$$d(L(z_1), L(z_2)) \leq a d(z_1, z_2).$$

Contraction Mapping

Example

Let $\mathcal{Z} = \mathbb{R}$ and $d(z_1, z_2) = |z_1 - z_2|$. Consider the mapping $L : z \mapsto az$ for $a \in \mathbb{R}$.

For any $z_1, z_2 \in \mathbb{R}$, we have

$$\begin{aligned} d(L(z_1), L(z_2)) &= |L(z_1) - L(z_2)| = |az_1 - az_2| \\ &= |a||z_1 - z_2| = |a|d(z_1, z_2). \end{aligned}$$

So if $|a| < 1$, this is a contraction mapping.

Why Do We Care About Contraction Mapping?

Some reasons:

- It describes the stability behaviour of a dynamical system.¹
 - ▶ Stability is related to the uniqueness of where the dynamical system converges.
- The contraction property can be used to show the uniqueness of solution of certain equations.
- The contraction property can sometimes be used when solving equations.

¹There are several notions of stability used in control theory.

Why Do We Care About Contraction Mapping?

As an example of its relation to stability, let $z_0 \in \mathcal{Z}$ and consider a mapping $L : z \mapsto az$ for some $a \in \mathbb{R}$. Define the dynamical system

$$\underline{z_{k+1}} = L\underline{z_k}, \quad k = 0, 1, \dots$$

The dynamical system described by this mapping generates

$$\begin{aligned}\underline{z_0} \\ \underline{z_1} &= \underline{az_0} \\ \underline{z_2} &= \underline{az_1} = \underline{a^2 z_0} \\ &\vdots \\ \underline{z_k} &= \underline{az_{k-1}} = \underline{a^k z_0}.\end{aligned}$$

Why Do We Care About Contraction Mapping?

$$z_k = a^k z_0.$$

- 
- If $|a| < 1$, z_k converges to zero, no matter what z_0 is.
 - If $a = 1$, we have $z_k = z_0$. So depending on z_0 , it converges to different points.
 - For $a = -1$, the sequence would oscillate between $+z_0$ and $-z_0$.
 - If $|a| > 1$, the sequence diverges (unless $z_0 = 0$).

Remark

The sequence is convergent whenever L is a contraction map.

Why Do We Care About Contraction Mapping?

Definition (Fixed Point)

If $L : \mathcal{Z} \rightarrow \mathcal{Z}$, then a point $z \in \mathcal{Z}$ such that

$$Lz = z$$

is called a fixed point of L .

Why Do We Care About Contraction Mapping?

The concept of fixed point and the solution of an equation is closely related.

Given an equation $f(z) = 0$, we can convert it to a fixed point equation $Lz = z$ by defining

$$\underline{L} : \underline{z} \mapsto \underline{f(\underline{z})} + \underline{z}.$$

Then, if $Lz^* = z^*$ for a z^* , we get that $f(z^*) = 0$, i.e., the fixed point of L is the same as the solution of $f(z) = 0$.

Banach Fixed Point Theorem

$$z_R = \frac{1}{R} \quad 0 \in \mathbb{Z}$$

$$(0, 1)$$

$$[0, 1]$$

Theorem (Banach Fixed Point Theorem)

If $L : \mathcal{Z} \rightarrow \mathcal{Z}$ is a contraction mapping on a complete metric space $(\mathcal{Z}, d)$, then there exists a unique $z^* \in \mathcal{Z}$ such that $Lz^* = z^*$.

Furthermore, the point z^* can be found by choosing an arbitrary $z_0 \in \mathcal{Z}$ and defining $z_{k+1} = Lz_k$. We have $z_k \rightarrow z^*$.

$$V_k \rightarrow V^{\pi*}$$

Simple Exercise

Exercise

Suppose that we want to solve $cz + b = 0$ for $z \in \mathbb{R}$ and constants $c, b \in \mathbb{R}$.

- Choose a mapping $L : \mathbb{R} \rightarrow \mathbb{R}$ such that its fixed point is the same as the solution of this equation.*
- For what range of c is this mapping a contraction?*
- Let $c = -0.5$ and $b = 1$. If we start from $z_0 = 0$, what is the sequence of z_0, z_1, z_2 that we obtain by computing $z_{k+1} = Lz_k$?*

Bellman Operator is a Contraction

Lemma (Contraction)

For any π , the Bellman operator T^π is a γ -contraction mapping. The Bellman optimality operator T^* is a γ -contraction mapping.

They are specifically γ -contraction w.r.t. the metric d defined based on the supremum norm: $d(V_1, V_2) = \|V_1 - V_2\|_\infty$ (and similar for Q). We have

$$\|TV_1 - TV_2\|_\infty \leq \gamma \|V_1 - V_2\|_\infty,$$

$$\|TQ_1 - TQ_2\|_\infty \leq \gamma \|Q_1 - Q_2\|_\infty.$$

$$T \rightarrow \begin{matrix} T^\pi \\ T^* \end{matrix}$$

Bellman Operator is a Contraction (Proof)

We only show it for the Bellman operator $T^\pi : \mathcal{B}(\mathcal{X} \times \mathcal{A}) \rightarrow \mathcal{B}(\mathcal{X} \times \mathcal{A})$.

Consider two action-value functions $Q_1, Q_2 \in \mathcal{B}(\mathcal{X} \times \mathcal{A})$.

Consider the metric $d(Q_1, Q_2) = \|Q_1 - Q_2\|_\infty$.

We show the contraction w.r.t. this metric.

For any $(x, a) \in \mathcal{X} \times \mathcal{A}$, we have

$$\begin{aligned}
 & |(T^\pi Q_1)(x, a) - (T^\pi Q_2)(x, a)| = \\
 & \left| \left[r(x, a) + \gamma \int \mathcal{P}(dx' | x, a) \pi(da' | x') \underline{Q_1(x', a')} \right] - \right. \\
 & \left. \left[r(x, a) + \gamma \int \mathcal{P}(dx' | x, a) \pi(da' | x') \underline{Q_2(x', a')} \right] \right| \\
 & = \gamma \left| \int \mathcal{P}(dx' | x, a) \pi(da' | x') (\underline{Q_1(x', a') - Q_2(x', a')}) \right|.
 \end{aligned}$$

Handwritten notes: Blue arrows point to the terms $r(x, a)$ and γ in both brackets. Green arrows point to the integral terms. A blue bracket underlines the difference $Q_1 - Q_2$ in the final line. A blue squiggle is at the bottom right.

Bellman Operator is a Contraction (Proof)

Let us upper bound the right-hand side (RHS).

We have an integral of the form $\left| \int P(dx) f(x) \right|$ (or a summation $\left| \sum_x P(x) f(x) \right|$ for a countable state space). This can be upper bounded as

$$\begin{aligned}
 \left| \int P(dx) f(x) \right| &\leq \int |P(dx) f(x)| = \int |P(dx)| \cdot |f(x)| \\
 &\leq \int P(dx) \sup_{x \in \mathcal{X}} |f(x)| \\
 &= \sup_{x \in \mathcal{X}} |f(x)| \underbrace{\int P(dx)}_{=1} = \|f\|_{\infty},
 \end{aligned}$$

where we used $\int P(dx) = 1$.

Bellman Operator is a Contraction (Proof)

In our case, we get that

$$\begin{aligned}
 & \rightarrow |(T^\pi Q_1)(x, a) - (T^\pi Q_2)(x, a)| = \\
 & \rightarrow \gamma \left| \int \mathcal{P}(\mathrm{d}x'|x, a) \pi(\mathrm{d}a'|x') (Q_1(x', a') - Q_2(x', a')) \right| \\
 & \leq \gamma \int \mathcal{P}(\mathrm{d}x'|x, a) \pi(\mathrm{d}a'|x') |Q_1(x', a') - Q_2(x', a')| \\
 & \leq \gamma \|Q_1 - Q_2\|_\infty \int \mathcal{P}(\mathrm{d}x'|x, a) \pi(\mathrm{d}a'|x') \\
 & = \gamma \|Q_1 - Q_2\|_\infty.
 \end{aligned}$$

This inequality holds for any $(x, a) \in \mathcal{X} \times \mathcal{A}$, so it holds for its supremum over $\mathcal{X} \times \mathcal{A}$ too, i.e.,

$$\| (T^\pi Q_1) - (T^\pi Q_2) \|_\infty \leq \gamma \|Q_1 - Q_2\|_\infty.$$

This shows that T^π is a γ -contraction.

Bellman Operator is a Contraction (Proof) - Discussion

Tips and Tricks

A commonly used proof and analysis strategy when we have terms in the form of $TQ_1 - TQ_2$ (or similar with V) is to get rid of the common terms (r) and try to move Q_1 and Q_2 close together. Depending on the application, we may use some form of upper bounding. Some commonly used inequalities are summarized in an appendix of the textbook.

Consequences of Monotonicity and Contraction

Consequences of Monotonicity and Contraction

Bellman operators are

- Monotonic
- γ -contraction

Several consequences:

- Bellman equations have unique fixed points.
- Error bounds on the difference between V and V^* when $V \approx T^*V$.
- V^* is the optimal value function V^{π^*} .
- An optimal policy belongs within the space of stationary policies.

Uniqueness of Fixed Points

Proposition (Uniqueness of Fixed Points)

The operators $\underline{T^\pi}$ and $\underline{T^*}$ have unique fixed points, denoted by $\underline{V^\pi}$ and $\underline{V^*}$, i.e.,

$$\underline{V^\pi} = \underline{T^\pi} \underline{V^\pi},$$

$$\underline{V^*} = \underline{T^*} \underline{V^*}.$$

They can be computed from any $\underline{V_0} \in \mathcal{B}(\mathcal{X})$ by iteratively computing $\underline{V_{k+1}} \leftarrow \underline{T^*} \underline{V_k}$ (and similar for $\underline{V^\pi}$ using $\underline{T^\pi}$ instead) for $k = 0, 1, \dots$. We have that $\underline{V_k} \rightarrow \underline{V^*}$ (and similarly, $\underline{V_k} \rightarrow \underline{V^\pi}$).

The same result is true for $\underline{Q^\pi}$ and $\underline{Q^*}$.

Uniqueness of Fixed Points (Proof)

- Consider the space of bounded functions $\mathcal{B}(\mathcal{X})$ with the metric d based on the uniform norm, i.e., $d(V_1, V_2) = \|V_1 - V_2\|_\infty$. The space $(\mathcal{B}(\mathcal{X}), d)$ is a complete metric space.
- For any π , the operator T^π is a γ -contraction. Likewise, T^* has the same property too (Lemma 13).
- By the Banach fixed point theorem (Theorem 12), they have a unique fixed point. Moreover, any sequence (V_k) with $V_0 \in \mathcal{B}(\mathcal{X})$ and $V_{k+1} \leftarrow T^\pi V_k$ ($k = 0, 1, \dots$) is convergent, which means that $\lim_{k \rightarrow \infty} \|V_k - V^\pi\|_\infty = 0$.

$$\hookrightarrow \|V_k - V^\pi\|_\infty = 0 \rightarrow V_k(\mathcal{X}) = V^\pi(\mathcal{X}) \quad \forall \mathcal{X}$$

Value of the Greedy Policy of V^* is V^*

Proposition

We have T^π V^* = T^* V^* if and only if V^π = V^* .

Value of the Greedy Policy of V^* is V^* (Proof) (†)

Proof of $T^\pi V^* = T^* V^* \implies V^\pi = V^*$:

Assume that $T^\pi V^* = T^* V^*$.

As V^* is the solution of the Bellman optimality equation, we have $T^* V^* = V^*$. Therefore,

$$T^\pi V^* = T^* V^* = V^*.$$

This shows that V^* is a fixed point of T^π .

The fixed point of T^π , however, is unique (Proposition 14) and is equal to V^π .

So V^π and V^* should be the same, i.e., $V^\pi = V^*$.

Value of the Greedy Policy of V^* is V^* (Proof) (†)

Proof of $V^\pi = V^* \implies T^\pi V^* = T^* V^*$:

We apply T^π to both sides of $V^* = V^\pi$ to get

$$T^\pi V^* = T^\pi V^\pi.$$

As V^π is the solution of the Bellman equation for policy π , we have $T^\pi V^\pi = V^\pi$. Therefore,

$$T^\pi V^* = T^\pi V^\pi = V^\pi.$$

By assumption, $V^\pi = V^*$. So we have $T^\pi V^* = V^\pi = V^*$.

On the other hand, we have $V^* = T^* V^*$, so

$$T^\pi V^* = V^* = T^* V^*,$$

which is the desired result.

Value of the Greedy Policy of V^* is V^*

Discussion:

- If $T^\pi \underline{V^*} = \underline{T^* V^*}$ for some policy π , the value function $\underline{V^\pi}$ of that policy is the same as the fixed point of T^* , which is $\underline{V^*}$.
- We have not yet shown that the fixed point of T^* is an optimal value function, in the sense that it is

$$\pi^* \leftarrow \operatorname{argmax}_{\pi \in \Pi} V^\pi(x) \quad (\text{for all } x \in \mathcal{X})$$

over the space of all stationary policies Π (or even more generally, over the set of all non-stationary policies)

- But it is indeed true!

Value of the Greedy Policy of V^* is V^*

To see the connection to the greedy policy:

- Given V^* , the greedy policy selects $\pi_g(x; V^*) = \operatorname{argmax}_{a \in \mathcal{A}} \{r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) V^*(x')\}$.
- So $T^{\pi_g(V^*)} V^* = \max_{a \in \mathcal{A}} \{r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) V^*(x')\}$
- Compare with $T^* V^*$, i.e., $(T^* V^*)(x) = \max_{a \in \mathcal{A}} \{r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) V^*(x')\}$.
- So $T^{\pi_g(V^*)} V^* = T^* V^*$.
- This proposition states that the value of following $\pi_g(V^*)$, that is $V^{\pi_g(V^*)}$, is the same as V^* .
- If we find V^* and its greedy policy $\pi_g(V^*)$, the value of following the greedy is V^* .
- Practical Consequence:** To find an optimal policy, we can find V^* first and then follow its greedy policy $\pi_g(V^*)$. This is the basis of many Planning and RL algorithms.

What if $V \approx T^*V$?

- If we find a V such that $V = T^*V$, we know that $V = V^*$ (similar for T^π and Q).
- What if $V \approx T^*V$? What can be said about the closeness of V to V^* ?
- Practically important, because we often can only solve the Bellman equations approximately, because of various sources of errors
 - ▶ Computational
 - ▶ Function Approximation
 - ▶ Statistical

An Error Bound based on the Bellman Error

$$V^* = T^* V^* \quad V \approx TV$$

$$BR(V) = V - TV$$

Proposition

For any $V \in \mathcal{B}(\mathcal{X})$ or $Q \in \mathcal{B}(\mathcal{X} \times \mathcal{A})$, we have

$$\|V - V^*\|_\infty \leq \frac{\|V - T^*V\|_\infty}{1 - \gamma}, \quad \|Q - Q^*\|_\infty \leq \frac{\|Q - T^*Q\|_\infty}{1 - \gamma}.$$

The quantity $BR(V) \triangleq T^\pi V - V$ and $BR^*(V) \triangleq T^*V - V$ are called **Bellman Residuals**.

Their norms are called **Bellman Errors**.

An Error Bound based on the Bellman Error (Proof)

We want to upper bound $\|V - V^*\|_\infty$.

We start from $V - V^*$, and add and subtract T^*V to $V - V^*$.

We then take the supremum norm, and use the triangle inequality to get

$$\begin{aligned}
 \rightarrow V - V^* &= V - \underbrace{T^*V + T^*V}_{\text{orange box}} - V^* \\
 \Rightarrow \|V - V^*\|_\infty &= \|\underbrace{V - T^*V}_{\text{blue underline}} + \underbrace{T^*V - V^*}_{\text{blue underline}}\|_\infty \\
 &\leq \underbrace{\|V - T^*V\|_\infty}_{\text{blue underline}} + \underbrace{\|T^*V - V^*\|_\infty}_{\text{blue underline}}.
 \end{aligned}$$

Handwritten annotations: A green arrow points from the first term $\|V - T^*V\|_\infty$ back to the first term in the first equation. A blue arrow points from the second term $\|T^*V - V^*\|_\infty$ to the second term in the first equation. A green arrow points from the second term in the first equation to the second term in the second equation. A blue question mark is next to the second term in the second equation.

An Error Bound based on the Bellman Error (Proof)

Let us focus on the term $\|T^*V - V^*\|_\infty$. Two observations:

- $V^* = T^*V^*$.
- The Bellman optimality operator is a γ -contraction w.r.t. the supremum norm.

Thus,

$$\|T^*V - V^*\|_\infty = \|T^*V - T^*V^*\|_\infty \leq \underline{\gamma} \|V - V^*\|_\infty.$$

Therefore,

$$\underline{\|V - V^*\|_\infty} \leq \|V - T^*V\|_\infty + \underline{\gamma} \|V - V^*\|_\infty.$$

Re-arranging this, we get

$$(1 - \gamma) \|V - V^*\|_\infty \leq \|V - T^*V\|_\infty.$$

An Error Bound based on the Bellman Error (for policy π)

Proposition

For any $V \in \mathcal{B}(\mathcal{X})$ or $Q \in \mathcal{B}(\mathcal{X} \times \mathcal{A})$, and any $\pi \in \Pi$, we have

$$\|V - V^\pi\|_\infty \leq \frac{\|V - T^\pi V\|_\infty}{1 - \gamma}, \quad \|Q - Q^\pi\|_\infty \leq \frac{\|Q - T^\pi Q\|_\infty}{1 - \gamma}.$$

Conservative

An Error Bound based on the Bellman Error (Proof) - Discussion

Tips and Tricks

Three high-level ideas are used in this proof that sometimes appear in the proof of these kinds of upper bounds involving value functions and the Bellman operator.

- Adding and subtracting equal terms ($\pm T^*V$ in this proof) in order to get terms in familiar or intended form ($T^*V - V$ here).
- Benefitting from the fixed-point property of the Bellman operator. We convert $T^*V - V^*$, not “balanced” in terms of the application of the Bellman operator, to $T^*V - T^*V^*$, which is balanced.
- Benefitting from the contraction property of the Bellman operator, as we have $T^*V - T^*V^*$.

V^* is the same as V^{π^*}

The fixed point of T^* is indeed the optimal value function within the space of stationary policies Π .

We use the monotonicity of T^* , in addition to contraction, to prove it.

V^* is the same as V^{π^*}

Proposition

Let V^* be the fixed point of T^* , i.e., $V^* = T^*V^*$. We have

$$V^*(x) = \sup_{\pi \in \Pi} V^\pi(x), \quad \forall x \in \mathcal{X}.$$

Recall that Π is the space of stationary Markov policies.

We skip the proof! You can read it in the Foundations of Reinforcement Learning [Farahmand, 2025].

V^* is the same as V^{π^*} (Proof) (†)

Overview:

- We show that $V^*(x) \leq \sup_{\pi \in \Pi} V^{\pi}(x)$.
- We show that $\sup_{\pi \in \Pi} V^{\pi}(x) \leq V^*(x)$.
- Combined, they show that $V^*(x) = \sup_{\pi \in \Pi} V^{\pi}(x)$.

V^* is the same as V^{π^*} (Proof) (†)

Proof of $V^*(x) \leq \sup_{\pi \in \Pi} V^\pi(x)$:

From the error bound result (Proposition 17) with the choice of $V = V^*$, we get that for any $\pi \in \Pi$,

$$\|V^* - V^\pi\|_\infty \leq \frac{\|V^* - T^\pi V^*\|_\infty}{1 - \gamma}. \quad (8)$$

Let $\varepsilon > 0$. Choose a policy π_ε such that

$$\|V^* - T^{\pi_\varepsilon} V^*\|_\infty \leq (1 - \gamma)\varepsilon.$$

This is possible because we have

$$(T^* V^*)(x) = \sup_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(\mathrm{d}x' | x, a) V^*(x') \right\},$$

so it is sufficient to pick a π_ε that solves the optimization problem up to $(1 - \gamma)\varepsilon$ -accuracy of the supremum at each state x (if we find the maximizer, then $\varepsilon = 0$).

V^* is the same as V^{π^*} (Proof) (†)

Proof of $V^*(x) \leq \sup_{\pi \in \Pi} V^\pi(x)$ (Continued):

For policy π_ε , (8) shows that

$$\|V^* - V^{\pi_\varepsilon}\|_\infty \leq \varepsilon.$$

This means that

$$V^*(x) \leq V^{\pi_\varepsilon}(x) + \varepsilon, \quad \forall x \in \mathcal{X}.$$

Notice that $V^{\pi_\varepsilon}(x) \leq \sup_{\pi \in \Pi} V^\pi(x)$ (as $\pi_\varepsilon \in \Pi$). We take $\varepsilon \rightarrow 0$ to get that for all $x \in \mathcal{X}$,

$$V^*(x) \leq \lim_{\varepsilon \rightarrow 0} \{V^{\pi_\varepsilon}(x) + \varepsilon\} \leq \lim_{\varepsilon \rightarrow 0} \left\{ \sup_{\pi \in \Pi} V^\pi(x) + \varepsilon \right\} = \sup_{\pi \in \Pi} V^\pi(x). \quad (9)$$

This shows that V^* , the fixed point of T^* , is smaller or equal to the optimal value function within the space of stationary policies.

V^* is the same as V^{π^*} (Proof) (†)

Proof of $\sup_{\pi \in \Pi} V^\pi(x) \leq V^*(x)$:

Consider any $\pi \in \Pi$. By the definition of T^π and T^* , for any $V \in \mathcal{B}(\mathcal{X})$, we have that for any $x \in \mathcal{X}$,

$$\begin{aligned}(T^\pi V)(x) &= \int \pi(da|x) \left[r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) V(x') \right] \\ &\leq \sup_{a \in \mathcal{A}} \left\{ r(x, a) + \gamma \int \mathcal{P}(dx'|x, a) V(x') \right\} \\ &= (T^*V)(x).\end{aligned}$$

In particular, with the choice of $V = V^*$, we have

$$T^\pi V^* \leq T^*V^*.$$

V^* is the same as V^{π^*} (Proof) (†)

Proof of $\sup_{\pi \in \Pi} V^\pi(x) \leq V^*(x)$ (Continued):

$$T^\pi V^* \leq T^* V^*.$$

As $T^* V^* = V^*$, we have

$$T^\pi V^* \leq V^*. \tag{10}$$

We use the monotonicity of T^π (Lemma 3) to conclude that

$$T^\pi(T^\pi V^*) \leq T^\pi V^*,$$

which by (10) shows that

$$(T^\pi)^2 V^* \leq V^*.$$

We repeat this argument for k times to get that

$$(T^\pi)^k V^* \leq V^*.$$

V^* is the same as V^{π^*} (Proof) (†)

Proof of $\sup_{\pi \in \Pi} V^{\pi}(x) \leq V^*(x)$ (Continued):

$$(T^{\pi})^k V^* \leq V^*.$$

As $k \rightarrow \infty$, Proposition 14 shows that $(T^{\pi})^k V^*$ converges to V^{π} (the choice of V^* is irrelevant). Therefore,

$$V^{\pi} = \lim_{k \rightarrow \infty} (T^{\pi})^k V^* \leq V^*.$$

As this holds for any $\pi \in \Pi$, we take the supremum over $\pi \in \Pi$ to get

$$\sup_{\pi \in \Pi} V^{\pi} \leq V^*. \quad (11)$$

Inequalities (9) and (11) together show the desired result.

A New Notation: $\mathcal{P}f$

Definition

Given the transition probability kernel $\mathcal{P}$ and a function $f \in \mathcal{B}(\mathcal{X})$, we define $\mathcal{P}f : \mathcal{X} \times \mathcal{A} \rightarrow \mathbb{R}$ as the function

$$(\mathcal{P}f)(x, a) \triangleq \int_{\mathcal{X}} \mathcal{P}(\mathrm{d}y | x, a) f(y), \quad \forall (x, a) \in \mathcal{X} \times \mathcal{A}.$$

Likewise, given the transition probability kernel induced by a policy π , we define $\mathcal{P}^\pi f : \mathcal{X} \rightarrow \mathbb{R}$ as $(\mathcal{P}^\pi f)(x) \triangleq \int_{\mathcal{X}} \mathcal{P}^\pi(\mathrm{d}y | x) f(y)$ for all $x \in \mathcal{X}$.

$\mathcal{P}^\pi f$ is the function whose value at a state x is the expected value of function f according to the distribution $\mathcal{P}^\pi(\cdot | x)$, that is,

$$(\mathcal{P}^\pi f)(x) = \mathbb{E}_{X' \sim \mathcal{P}^\pi(\cdot | x)} [f(X')].$$

In our applications, f is usually a function with the semantic of the value function, that is, V or Q .

Following a Sequence of Policies

$$\mathcal{P}^\pi \quad (\mathcal{P}^\pi)^m$$

For a sequence of policies $\pi_{1:m} = (\pi_1, \dots, \pi_m)$, the transition probability kernel of following them in the order of π_1 , then π_2 , etc., is denoted by $\mathcal{P}^{\pi_1:\pi_m}$ or $\mathcal{P}^{\pi_{1:m}}$ and is

$$\mathcal{P}^{\pi_{1:m}}(A|x) \triangleq \int_{\mathcal{X}} \mathcal{P}^{\pi_1}(dy|x) \mathcal{P}^{\pi_{2:m}}(A|y),$$

$$\mathcal{P}^{\pi_{1:m}}(B|x, a) \triangleq \int_{\mathcal{X}} \mathcal{P}(dy|x, a) \mathcal{P}^{\pi_{2:m}}(A|y),$$

for deterministic policies, and similar for stochastic policies.
This is the generalization of $\mathcal{P}^\pi$ when $\pi_{1:m} = (\underbrace{\pi, \dots, \pi}_m)$.

Sequence of the Bellman Operators

Suppose that we have two policies π_1 and π_2 . What is the meaning of the operator $T^{\pi_1}T^{\pi_2}$?

To understand what it does, consider a value function V , and see what the effect of $T^{\pi_1}T^{\pi_2}$ on V is.

Denote $T^{\pi_2}V$ by U . We have

$$(T^{\pi_1}T^{\pi_2}V)(x) = (T^{\pi_1}U)(x) = r^{\pi_1}(x) + \gamma \int \mathcal{P}^{\pi_1}(dz|x)U(z).$$

The function U at state $z \in \mathcal{X}$ is

$$U(z) = (T^{\pi_2}V)(z) = r^{\pi_2}(z) + \gamma \int \mathcal{P}^{\pi_2}(dy|z)V(y).$$

Sequence of the Bellman Operators

Combining these two equations, we get

$$\begin{aligned}
 (T^{\pi_1} T^{\pi_2} V)(x) &= \\
 r^{\pi_1}(x) + \gamma \int \mathcal{P}^{\pi_1}(dz|x) \left[r^{\pi_2}(z) + \gamma \int \mathcal{P}^{\pi_2}(dy|z) V(y) \right] &= \\
 r^{\pi_1}(x) + \gamma \int \mathcal{P}^{\pi_1}(dz|x) r^{\pi_2}(z) + \gamma^2 \int \mathcal{P}^{\pi_1}(dz|x) \mathcal{P}^{\pi_2}(dy|z) V(y) &= \\
 r^{\pi_1}(x) + \gamma(\mathcal{P}^{\pi_1} r^{\pi_2})(x) + \gamma^2(\mathcal{P}^{\pi_1:\pi_2} V)(x).
 \end{aligned}$$

Therefore, the function $T^{\pi_1} T^{\pi_2} V$ is

$$T^{\pi_1} T^{\pi_2} V = \underline{r^{\pi_1}} + \gamma \underline{\mathcal{P}^{\pi_1}} \underline{r^{\pi_2}} + \underline{\gamma^2 \mathcal{P}^{\pi_1:\pi_2} V},$$

and the operator $T^{\pi_1} T^{\pi_2} : \mathcal{B}(\mathcal{X}) \rightarrow \mathcal{B}(\mathcal{X})$ is

$$\underline{T^{\pi_1} T^{\pi_2}} : \underline{V} \mapsto \underline{r^{\pi_1} + \gamma \mathcal{P}^{\pi_1} r^{\pi_2} + \gamma^2 \mathcal{P}^{\pi_1:\pi_2} V}.$$

Sequence of the Bellman Operators

For a sequence of policies $\pi_1, \dots, \pi_m$, we have

$$\begin{aligned}
 T^{\pi_1} T^{\pi_2} \dots T^{\pi_m} V &= \\
 r^{\pi_1} + \gamma \mathcal{P}^{\pi_1} r^{\pi_2} + \gamma^2 \mathcal{P}^{\pi_1:\pi_2} r^{\pi_3} + \dots + \gamma^{m-1} \mathcal{P}^{\pi_1:\pi_{m-1}} r^{\pi_m} + \gamma^m \mathcal{P}^{\pi_1:\pi_m} V \\
 &= \sum_{k=1}^m \gamma^{k-1} \mathcal{P}^{\pi_1:\pi_{k-1}} r^{\pi_k} + \gamma^m \mathcal{P}^{\pi_1:\pi_m} V.
 \end{aligned}$$

Interpretation: the function $\underbrace{T^{\pi_1} T^{\pi_2} \dots T^{\pi_m}}_{\bar{T}}$ V is the value function of following the non-stationary policy $\bar{\pi} = (\pi_1, \dots, \pi_m)$ in a finite horizon MDP with the terminal reward of $\underline{V}$.

Summary

- Bellman equations describe an important recursive properties of value functions.
- Bellman operators T^π and T^* .
- Greedy policy and the optimal policy.
- Monotonicity and contraction properties of the Bellman operators.
- Bellman equations have unique solutions.
- Bellman error $\|V - T^*V\|_\infty$ provides an upper bound on value error $\|V - V^*\|_\infty$.
- The solution of the Bellman optimality equation is the optimal value function.
- The interpretation of $T^{\pi_1}T^{\pi_2} \dots T^{\pi_m}V$.
